Introduction

Many philosophers (myself included) have been converted to causal decision theory by something like the following line of argument: Evidential decision theory endorses irrational courses of action in a range of examples, and endorses “an irrational policy of managing the news”. These are fatal problems for evidential decision theory. Causal decision theory delivers the right results in the troublesome examples, and does not endorse this kind of irrational news-managing. So we should give up evidential decision theory, and be causal decision theorists instead.

Unfortunately, causal decision theory has its own family of problematic examples for which it endorses irrational courses of action, and its own irrational policy that it is committed to endorsing. These are, I think, fatal problems for causal decision theory. I wish that I had another theory to offer in its place.

1. The Case against Evidential Decision Theory

Evidential decision theory says that the action that it’s rational to perform (ignoring the possibility of ties) is the one with the greatest expected utility – the one such that your expectations for how the world will turn out, conditional on your

---

1 Special thanks are due to David Braddon-Mitchell for the series of conversations that led to this paper, and for many further conversations as it was in progress. Thanks also to Adam Elga, Brian Weatherson, Karen Bennett, Daniel Stoljar, Alan Hajek, James Joyce, and audiences at the University of Pittsburgh, Oxford University, and the ANU Philosophical Society for very helpful questions, comments, and objections.

2 Lewis (1981)
performing it, are greater than the expectations conditional on performing some other action. So the action that it’s rational to perform will also be the one that you (or a friend with you’re your own interests in mind, and with the same ideas about where your interests lie as you have) would be happiest to learn that you had performed. The case against evidential decision theory is based upon examples like the following:

*The Smoking Lesion*

Susan is debating whether or not to smoke. She knows that smoking is strongly correlated with lung cancer, but only because there is a common cause – a condition that tends to cause both smoking and cancer. Once we fix the presence or absence of this condition, there is no additional correlation between smoking and cancer. Susan prefers smoking without cancer to not smoking without cancer, and prefers smoking with cancer to not smoking with cancer. Should Susan smoke? It seems clear that she should. (Set aside your theoretical commitments and put yourself in Susan’s situation. Would *you* smoke? Would you take yourself to be irrational for doing so?)

Causal decision theory distinguishes itself from evidential decision theory by delivering the right result for *The Smoking Lesion*, where its competition – evidential decision theory – does not. The difference between the two theories is in how they compute the relative value of actions. Roughly: evidential decision theory says to do the

---

3 This example is a standard medical Newcomb problem, representative of the many to be found in the literature. The original Newcomb’s problem is from Nozick (19xx). For some excellent discussions of medical (and other) Newcomb problems, see Gibbard and Harper (1976), Eells (19xx), Lewis (19xx, 19xx)... MORE
thing you’d be happiest to learn that you’d done, and causal decision theory tells you to
do the thing most likely to bring about good results.

Evidential decision theory tells Susan not to smoke, roughly because it treats the
fact that her smoking is evidence that she has the lesion, and therefore is evidence that
she is likely to get cancer, as a reason not to smoke. Causal decision theory tells her to
smoke, roughly because it does not treat this sort of common-cause based evidential
connection between an action and a bad outcome as a reason not to perform the action.
Let’s look at how the differences between the formal theories deliver these results:

Following Lewis, let a *dependency hypothesis* be a proposition which is
maximally specific about how things that the agent cares about depend causally on what
the agent does. Also following Lewis, let us think of such propositions as long
conjunctions of subjunctive conditionals (of the appropriate, non-backtracking kind) of
the form, *if I were to do A, then P*. (Written, from now on, “A → P”.)

The difference between causal and evidential decision theory is that causal
decision theory privileges the agent’s prior assignment of credences to dependency
hypotheses in determining the relative values of actions.

If the H’s form a partition of the worlds that the agent assigns non-zero credence,
the value assigned to an action A by evidential decision theory (henceforth EDT) is given
by:

\[ \text{VAL}_{\text{EDT}} = \sum H \text{c}(H|A)v(HA) \]

(Note a harmless ambiguity: I’m using ‘A’ to name both an action and the proposition
that the agent performs that action.)
In particular, in the case of the partition of dependency hypotheses (let these be the Ks), the value assigned by EDT is given by:

\[ \text{VAL}_{\text{EDT}} = \sum_{K \cap A} c(K\mid A)v(KA) \]

The important thing to notice about this formula is that it’s the agent’s *conditional* credences in dependency hypotheses that figure in it.

The value assigned by causal decision theory (henceforth CDT) is given by:

\[ \text{VAL}_{\text{CDT}} = \sum_{K} c(K)v(KA) \]

The crucial difference is that now the assignments of values to actions are sensitive only to the agent’s *unconditional* credences in dependency hypotheses, not her credences conditional on her performing A. The effect of this is to hold fixed the agent’s beliefs about the causal structure of the world, and force us to use the same beliefs about the causal order of things in determining the choiceworthiness of each candidate action. Rather than the expected payoffs of smoking being determined by reference to Susan’s how Susan thinks the causal structure of the world is likely to be, *conditional on her smoking*, and the expected payoffs of not smoking determined by reference to how she thinks the causal structure of the world is likely to be, *conditional on her not smoking*, the expected payoffs of both smoking and not smoking are determined by reference to Susan’s *initial* beliefs about how the causal structure of the world is likely to be.

It is cases like *The Smoking Lesion* motivate the move from EDT to CDT. In *The Smoking Lesion*, there is a strong correlation between smoking and getting cancer, despite the fact that smoking has no tendency to *cause* cancer, due to the fact that smoking and cancer have a common cause. Still, since Susan’s \( c(\text{CANCER}\mid \text{SMOKE}) \) is
much higher than her c(CANCER\|NOT SMOKE), EDT assigns not smoking a higher value than smoking. And this seems wrong.

So we have an argument against EDT: The correct theory of rational decision won’t endorse any irrational actions or policies. In *The Smoking Lesion*, EDT endorses an irrational course of action: it’s irrational for Susan not to smoke, and EDT endorses not smoking. EDT also endorses an irrational policy: it endorses a policy of performing the action with the greatest *evidential* value, rather than the action with the best expected causal upshot. So EDT isn’t the correct theory of rational decision.

CDT, on the other hand, uses the agent’s *unconditional* credences in dependency hypotheses to assign values to actions. The effect of this is to make our assignments of values to actions blind to the sort of common-cause correlations that make EDT’s value assignments in *The Smoking Lesion* go bad.

Causal decision theory now looks very attractive. It gets the cases that made trouble for EDT right, and it seems to get them right for the right reasons – by assigning the agent’s causal beliefs a special role.

3. The Case against Causal Decision Theory

Causal decision theory is supposed to be a formal way of cashing out the slogan, “do what you expect will bring about the best results”. The way of implementing this sound advice is to hold fixed the agent’s prior credences in dependency hypotheses. The resulting theory enjoins us to *do whatever has the best expected outcome, holding fixed out initial views about the likely causal structure of the world*. The following examples
show that these two principles come apart, and that where they do, causal decision theory
does not endorse irrational courses of action.

(Obviously I think that each of the cases succeeds in showing this. But it’s not
important that you agree with me about both cases. For my purposes, all I need is one
case.)

*The Murder Lesion*

Mary is debating whether to shoot Alfred. If she shoots and hits, things will
be very good for her. If she shoots and misses, things will be very bad. (Alfred
always finds out about unsuccessful assassination attempts, and he is sensitive
about such things.) If she doesn’t shoot, things will go on in the usual, okay-but-
not-great kind of way. She thinks that it is very likely that, if she were to shoot,
then she would hit. So far, so good. But Mary also knows that there is a certain
sort of brain lesion that tends to cause both murder attempts and bad aim at the
critical moment. Happily for most of us (but not so happily for Mary) most
shooters have this lesion, and so most shooters miss. Should Mary shoot? (Set
aside your theoretical commitments and put yourself in Mary’s situation. Would
*you* shoot? Would you take yourself to be irrational for not doing so?)

*The Psychopath Button*\(^4\)

Paul is debating whether to press the ‘kill all psychopaths’ button. It would,
he thinks, be much better to live in a world with no psychopaths. Unfortunately,

Paul is quite confident that only a psychopath would press such a button. Paul

---

\(^4\) This case was suggested by David Braddon-Mitchell.
very strongly prefers living in a world with psychopaths to dying. Should Paul press the button? (Set aside your theoretical commitments and put yourself in Paul’s situation. Would you press the button? Would you take yourself to be irrational for not doing so?)

It’s irrational for Mary to shoot. It’s irrational for Paul to press. In general, when you are faced with a choice of two options, it’s irrational to choose the one that you confidently expect will cause the worse outcome. Causal decision theory endorses shooting and pressing. In general, causal decision theory endorses, in these kinds of cases, an irrational policy of performing the action which one confidently expects will cause the worse outcome. The correct theory of rational decision will not endorse irrational actions or policies. So causal decision theory is not the correct theory of rational decision.

What’s generating the problem is that the very same mechanism that allows causal decision theory to deliver the right results in cases like The Smoking Lesion leads it to deliver the wrong results for cases like The Murder Lesion and The Psychopath Button.

Let’s look at what happens in The Murder Lesion. (The analysis of The Psychopath Button will be relevantly similar.) Let S be the proposition that Mary shoots,

---

5 Some people report that they lack the clear intuition of irrationality for the Murder Lesion case. Pretty much everyone seems to have the requisite intuition for The Psychopath Button, though. That’s enough for my purposes. Personally, I think both cases work as counterexamples to causal decision theory. But all I need is that at least one of them does.

6 Whether it’s irrational in a particular case depends, of course, on just what the payoffs are. It can be worth doing something that’s more likely than not to cause a bad outcome if the low-probability good outcome is good enough. But in the cases above (and as spelled out below), it’s better not to do the thing that you expect will cause the worse outcome. See below for some sample numbers.
and H the proposition that Mary hits. The relevant partition of dependency hypotheses is \{S \rightarrow H, S \rightarrow \neg H\}.

Some constraints on Mary’s credences:

\(c(S \rightarrow H) > .5\).

(Because she’s been going to the shooting range, the gun is well-maintained and reliable, Alfred is a large, slow-moving target, etc.)

\(c(S \rightarrow H|S) < .5\)

(Because if she shoots, it’s very likely because she has the lesion, and if she has the lesion, she’s very likely to have bad aim when push comes to shove.)

Mary's value assignments:

\(v(S.H) = 10\)

\(v(S.\neg H) = -10\)

\(v(\neg S) = 0\)

If Mary is a causal decision theorist, she must use \(c(S \rightarrow H)\), not \(c(S \rightarrow H|S)\), when she's determining the relative values of shooting or not. (Since it’s unconditional credences in dependency hypotheses that feature in CDT’s formula for determining the choiceworthiness of actions.) So shooting is going to come out better than not shooting.\(^8\)

\(^7\) Note, for future reference, that \(c(S)\) must be < .5 for these credences to be coherent.

\(^8\) Because CDT says that Mary should determine the value of smoking by computing: \(\Sigma_K c(K)v(KA)\), which in this case gives us:
But that’s the wrong result. It’s irrational for Mary to shoot. Unfortunately, if that’s right, then causal decision theory is wrong.

The same phenomenon occurs in a particularly striking way in time travel cases. Suppose that you have a time machine, and you are convinced that time travel works in the single-timeline, no-branching way outlined by Lewis (1976). You want to use your time machine to preserve some document, thought to be lost in the fire at the library of Alexandria. One option is to attempt to surreptitiously spirit the document out of the library before the fire. Another is to attempt to prevent the fire from ever happening. If you don’t have a firm opinion about which course you’ll actually pursue, you’re likely to be confident that, if you were to attempt to prevent the fire, you would succeed. (After all, you’re competent and knowledgeable, you have many willing and able accomplices and excellent equipment, etc.)

But you know that the fire really did happen. So you know that any attempt you make to go back and prevent it will fail.\(^9\) It’s irrational to pursue this sort of doomed plan, and so it’s irrational to try to prevent the fire. (Similarly, when you go back in time to set up a holding company that will, when the investments mature, pay a large lump sum into your bank account, you should arrange for the cash to be deposited in your account after the last time you checked your balance and saw that there hadn’t been any large deposits.)

But CDT doesn’t deliver these results. Determining the relative choiceworthiness of

\[
\text{VAL}_{\text{CDT}}(S) = c(S \rightarrow H)v(S \rightarrow H & S) + c(S \rightarrow \neg H)v(S \rightarrow \neg H & S)
\]

Assuming that Mary doesn’t care about dependency hypotheses for their own sakes, \(v(S \rightarrow H & S) = v(S,H)\), and \(v(S \rightarrow \neg H & S) = v(S,\neg H)\). (The value of shooting while in a Shoot \(\rightarrow\) Hit world is the value of shooting and hitting; the value of shooting while in a Shoot \(\rightarrow\) Miss world is the value of shooting and missing.) So we get:

\[
\text{VAL}_{\text{CDT}}(S) = c(S \rightarrow H)v(S,H) + c(S \rightarrow \neg H)v(S,\neg H)
\]

And since \(c(S \rightarrow H) > c(S \rightarrow \neg H)\), it will turn out that \(\text{VAL}_{\text{CDT}}(S) > c(S \rightarrow \neg H)\), it will turn out that \(\text{VAL}_{\text{CDT}}(S) > 0\), and so \(\text{VAL}_{\text{CDT}}(S) > V(\neg S)\).

As Lewis (1981) points out, other formulations of causal versions of decision theory deliver the same results.

\(^9\) There are complications. Some of these are discussed in Braddon-Mitchell and Egan (MS).
actions using only your *prior* credences in dependency hypotheses makes your ranking of actions insensitive to your knowledge – knowledge to which your decision-making *should* be sensitive – that the past-changing plans are doomed.

Oracle cases are relevantly similar. It’s irrational to try to avoid the fate that the (infallible) oracle predicts for you. The thing to do, faced with an unpleasant oracular prediction, is to try to ensure that the predicted fate comes about in the best possible way. If the oracle predicts that you’ll be bitten by a rabid dog, the thing to do is to wear thick clothes so the bite won’t do much harm, not to poison your neighbors’ dogs in hopes of avoiding the bite.

(It’s worth pointing out that neither the oracle nor the time-travel cases rely on absolute certainty. What’s really going on is that, the more reliable you take the oracle, or your information about the past, to be, the worse an idea it is to try to avert the predicted fate, or change the apparent past.)

I include the time travel and oracle cases because (a) they provide particularly stark examples of cases where CDT endorses performing an action that one confidently expects will bring about a worse outcome than some alternative, and (b) they may serve to make clearer just what’s gone wrong in the other cases. In these cases, just as in cases like *The Murder Lesion* and *The Psychopath Button*, the fact that CDT forces us to use only the agent’s prior credences in dependency hypotheses in determining the choiceworthiness of actions makes its verdicts blind to features of the agent’s beliefs to which it should be sensitive – namely, the agent’s confidence that a particular course of action, if undertaken, is doomed to fail, and bring about a worse outcome than the alternative.
I don’t want to rest very much argumentative weight on the time travel and oracle cases, since it’s not completely obvious how big a problem it is for CDT to give the wrong results in these peculiar sorts of situations – perhaps it’s okay to just bite the bullet here. In fact, I don’t think that this is very attractive, but it doesn’t really matter. Even if it is okay to bite the bullet in time travel and oracle cases, it’s not okay to bite the bullet on *The Murder Lesion* and *The Psychopath Button*. Or at least – and this is enough for my purposes – it’s not okay for the causal decision theorist to bite the bullet on *The Murder Lesion* and *The Psychopath Button* if it’s not okay for the evidential decision theorist to bite the bullet on *The Smoking Lesion*.

Here is the moral that I think we should draw from all of this: Evidential decision theory told us to perform the action with the best expected outcome. Examples like *The Smoking Lesion* show us that having the best expected outcome comes apart from having the best expected causal impact on how things are, and that rationality tracks the latter rather than the former. So, they show us that evidential decision theory is mistaken. Causal decision theory told us to perform the action which, *holding fixed our current views about the causal structure of the world*, has the best expected outcome. Examples like *The Murder Lesion* and *The Psychopath Button* show us that this too comes apart from having the best expected causal impact on how things are. So, they show us that causal decision theory is mistaken.

4. Objections, Responses, and Further Problems

There are some responses available to the causal decision theorist. Unfortunately, I don’t think that any of them work. In fact, the most promising response fails in a way
that shows us that the problem is actually quite a bit worse than I’ve suggested so far, and that the advocate of evidential decision theory ought to take no comfort in the difficulties for CDT.

Are the cases too science-fictional and/or morally loaded to make good counterexamples?

One might be concerned that the cases I’ve used against CDT – The Murder Lesion and The Psychopath Button – are either too science-fictional or too morally loaded to make good counterexamples, perhaps because our intuitions about such cases are not to be trusted. I’m inclined to insist on the legitimacy of the cases as given, but it’s not important that you agree with me. Once you know where to look, there are many more such cases to be found.

For example, it’s easy to modify The Smoking Lesion in order to make it a counterexample to CDT rather than EDT. We just have to change the case in the following way: Rather than letting the lesion (a) cause one to smoke, and (b) cause one to get cancer, let the lesion (a) cause one to smoke, and (b) cause one’s lungs to be vulnerable to cigarette smoke, such that smoking causes cancer in those with the lesion, but not in those without.

In this sort of situation, it is irrational to smoke. But CDT still endorses smoking. Further, this modified smoking lesion case is certainly not objectionably morally loaded. Nor is it objectionably science-fictional. At least, it’s not objectionably science-fictional unless the original Smoking Lesion case is objectionably science-fictional. So as long as The Smoking Lesion succeeds as a counterexample to EDT, the modified smoking lesion case will succeed as a counterexample to CDT.
This is an instance of a quite general recipe for generating counterexamples to CDT: Start with a counterexample to EDT in which some condition is a common cause both of some action A and of some undesirable outcome O. Change the case so that, rather than directly causing O, the condition puts in place an enabling condition which allows A to cause O. Note that one’s intuitions about what one ought to do switch when we change the causal background in this way, while CDT’s recommendations remain the same.  

These anti-CDT examples will be no more science-fictional or morally loaded than the original anti-EDT examples we started with. If the original examples were unacceptable, then CDT is unmotivated – we don’t have a counterexample to EDT. If the original examples were acceptable, then the modified examples are well, and CDT is subject to counterexamples. Neither outcome is a good one for the advocate of CDT.

Do the cases put unacceptable constraints on the agents’ credences regarding their own actions?

Notice that, in order for CDT to endorse shooting in *The Murder Lesion*, Mary must start off confident that, if she were to shoot, she would hit. For her to be confident of this, she must also start off confident that she does not have the lesion. And so she must start off confident that she will not shoot. Similarly, for CDT to endorse pressing in *The Psychopath Button*, Paul to start off confident that, if he were to press the button, he would live. For him to be confident of this, he must start off confident that he is not a psychopath. And so he must start off confident that he will not press the button. So in

---

10 Thanks to Martin Smith for pointing out this recipe.
order for my cases to work, the agents credences about what they are likely to do must be a certain fairly specific way. Is this a problem?

No. The cases do indeed place some constraints on the agents’ credences regarding their own future actions. But so too do the examples, like *The Smoking Lesion*, that motivate CDT over EDT. For those cases to succeed, the agents mustn’t be certain of what they’re going to choose. So if the fact that a case places *any* constraints on the agent’s credences about their own future actions renders it ineligible to serve as a counterexample, then the counterexamples to EDT will be ruled out along with the counterexamples to CDT, and CDT loses its motivation.

But perhaps it’s not the fact that a case places *some* constraints on the agent’s credences that rules it out as a counterexample, but the fact that it places a certain, objectionable *sort* of constraint on the agent’s credences, that rules it out as a counterexample. And while the counterexamples to EDT impose only innocent constraints, those imposed by the would-be counterexamples to CDT are objectionable.

I don’t think that there is any plausible way to cash out the distinction between innocent and objectionable constraints that will deliver this result. Certainly neither the counterexamples to EDT nor the counterexamples to CDT require the agents to have credences that violate the constraints of Bayesian rationality. And it’s unclear where else we might non-arbitrarily draw the line.

(Also, given the availability of the strategy for converting anti-EDT examples into anti-CDT examples outlined above, it looks as if there won’t be any sort of constraint that *only* the anti-CDT examples need to impose.)
Can we fix everything by going ratificationist?

Consider Paul’s situation as he deliberates about whether or not to press the ‘kill all psychopaths’ button. Suppose that Paul is an orthodox causal decision theorist. Pressing will, at the beginning of his deliberations, look better than refraining. Paul becomes convinced that pressing is the thing to do, and so he becomes convinced that he will, at the end of his deliberations, choose to press. But as Paul becomes more and more convinced that he’s going to choose to press, he becomes more and more confident that he’s a psychopath. And as he becomes more and more confident that he’s a psychopath, pressing will look like less and less of a good idea. At a certain point, as Paul becomes increasingly convinced that he’s going to press, CDT will stop telling him to press, and start telling him to refrain.

Pressing the psychopath button is unratifiable by the lights of CDT: it’s impossible for Paul both to be convinced that he will press the button, and also to rationally endorse doing so. It’s tempting to think that we can exploit this fact in order to save CDT from the apparent counterexamples, by imposing a ratifiability requirement on rational actions.

The simplest way to impose a ratifiability requirement is to simply add the following Maxim of Ratifiability to our original version of EDT:

Maxim of Ratifiability. An agent can rationally perform act $A$ only if $A$ is ratifiable in the sense that there is no alternative $B$ such that $\text{VAL}_{\text{CDT}}(B)$ exceeds $\text{VAL}_{\text{CDT}}(A)$ on the supposition that $A$ is decided upon.

The resulting theory tells us that it’s rational to perform an action $A$ iff:

1) $A$ is ratifiable

2) There is no other ratifiable option with greater (present) $\text{VAL}_{\text{CDT}}$ than $A$. 
A version of CDT that includes a ratifiability requirement will not endorse shooting in *The Murder Lesion*, or pressing in *The Psychopath Button*. When Mary becomes convinced that she will choose to shoot, shooting will look bad to her – $\text{VAL}_{\text{CDT}}(\text{SHOOT})$ will be less than $\text{VAL}_{\text{CDT}}(\text{NOT SHOOT})$. When Paul becomes convinced that he will choose to press, pressing will look bad to him – $\text{VAL}_{\text{CDT}}(\text{PRESS})$ will be less than $\text{VAL}_{\text{CDT}}(\text{NOT PRESS})$. So a theory that rules out unratifiable actions as irrational will not deliver the bad endorsements that we got from the version of CDT that did not include a ratifiability requirement.

There are two reasons why this response fails. The first, is that, if an appeal to ratifiability succeeds here, then the EDTer’s appeal to ratifiability in the cases that were supposed to motivate the move to CDT will succeed as well. (In fact, the appeal to ratifiability was originally a move in defense of EDT in the face of just such examples. See Jeffrey (1983).) In *The Smoking Lesion*, not smoking is unratifiable: once Susan becomes convinced that she will choose not to smoke, her smoking or not ceases to be evidence one way or the other for her having the lesion, and smoking looks better, by EDT’s lights, than not. So again, we have a situation in which, if the CDTer’s defense works, it works for the EDTer as well, and CDT loses its motivation. (But see Joyce (forthcoming) for an argument that the appeal to ratifiability is, in fact, only available to causal decision theorists.)

The second difficulty with this response is that it doesn’t do enough. Here are two constraints on any adequate theory of rational decision:
SOUNDNESS: If it’s irrational to $\varphi$, the correct theory of rational decision will not endorse $\varphi$ing.

COMPLETENESS: If it’s rational to $\varphi$, the correct theory of rational decision will endorse $\varphi$ing.

While the imposition of a ratifiability requirement prevents CDT from falling afoul of the SOUNDNESS requirement, the resulting theory falls afoul of COMPLETENESS.

In *The Psychopath Button*, it’s irrational for Paul to press. It’s rational for Paul to refrain from pressing. Neither action, however, is ratifiable. (When Paul becomes convinced that he will choose to refrain, he will become quite confident that he is not a psychopath, and pressing will look better than refraining.)

It’s rational for Paul to refrain. So the correct theory of rational decision will endorse refraining. Refraining is not ratifiable. So no theory that imposes a ratifiability requirement will endorse refraining. So no theory that imposes a ratifiability requirement is the correct theory of rational decision.\(^\text{11}\)

This shows us that imposing a ratifiability requirement will not help us to save CDT. It also shows us that what we have here is definitely not an argument for going back to EDT. These cases are all counterexamples to versions of EDT that impose

\(^{11}\) This, incidentally, also demonstrates the important difference between my cases and cases like Gibbard and Harper’s (1978) *Death in Damascus*, in which it’s also the case that neither option is ratifiable. In my cases, unlike in *Death in Damascus*, we still have clear intuitions about which action it’s rational to perform.
ratifiability requirements, as well, and these seem to be the only versions of EDT with the resources to deal with cases like *The Smoking Lesion*.

In fact, there are cases where imposing a ratifiability requirement makes things *worse*, particularly for CDT. Consider the following modification of the original Newcomb’s problem:

*Newcomb’s Firebomb*

There are two boxes before you. Box A definitely contains $1,000,000. Box B definitely contains $1,000. You have two choices: take only box A (call this *one-boxing*), or take both boxes (call this *two-boxing*). You will signal your choice by pressing one of two buttons. There is, as usual, an uncannily reliable predictor on the scene. If the predictor has predicted that you will two-box, he has planted an incendiary bomb in box A, wired to be detonated (burning up the $1,000,000) if you press the *two-box* button. If the predictor has predicted that you will one-box, no bomb has been planted – nothing untoward will happen, whichever button you press. The predictor, again, is uncannily accurate.

It is, I submit, rational to one-box, and irrational to two-box, in *Newcomb’s Firebomb*. (You should expect that, if you press the two-box button, you will be causing the incineration of your $1,000,000, which is certainly sitting there in Box A just waiting for you to carry it off to the bank. Crucially, it is *your choice* will cause its incineration – this is the key difference between *Newcomb’s Firebomb* and the original Newcomb’s problem.)
But neither option is ratifiable. A ratificationist theory will not endorse two-boxing, but it won’t endorse one-boxing either. So if we adopt a ratificationist theory, we will be forced to say that there is no rational option in this case. And this seems wrong – one boxing is pretty clearly the rational thing to do here.

The imposition of a ratifiability requirement makes things worse in this case, because versions of CDT that do not include a ratifiability requirement deliver, in almost every way of spelling out the case, the verdict that it’s rational to one-box. (The exceptions are cases in which one starts off extremely confident that one is going to choose one-boxing, and so starts off extremely confident that there is no bomb in box A.) Holding fixed any but the most extreme credences about whether or not there’s a bomb in box A, we get the result that one-boxing has greater $\text{VAL}_{\text{CDT}}$ than two-boxing. It is only in the cases where one assigns a very, very low initial credence to the presence of the firebomb that CDT will tell us that the possibility of gaining the extra $1,000 is worth the risk of setting fire to the $1,000,000.

So CDT without a ratifiability requirement almost always tells us, in accordance with our intuitions about the case, that it is rational to one-box, and irrational to two-box, in Newcomb’s Firebomb. In fact, the cases where it arguably goes wrong by endorsing two-boxing are ones where, perhaps, our intuitions are not so clear – after all, if you were that certain that there wasn’t a bomb, wouldn’t it really be worth the risk? Ratificationist versions of CDT, however, can never endorse one-boxing in Newcomb’s Firebomb. This is bad news, I think, for the ratificationist defense of CDT.

Conclusion
If all of the above is correct, causal decision theory is in a bad way. Either it’s subject to counterexamples, or there’s no reason to prefer it to EDT. That’s what I hope to have shown above, and that’s what I’m primarily concerned to emphasize in this concluding section. I will close, though, with some speculation about what’s gone wrong and the best way to fix it.

What conclusions should we draw from all this? Perhaps what these cases show that evidential decision theory was right after all: since everybody needs some tickle defense-ish move, we should be happy to make it right away, in the defense of EDT. I think, though, that this would be too hasty.

I take cases like The Smoking Lesion to show that EDT is informed by the wrong principle of rational decision. It’s informed by the principle (roughly), *do the thing which would give you the best evidence that the best things are happening*. Where the advice of this principle comes apart from that of the principle, *do what’s most likely to bring about the best results*, it delivers advice that it’s irrational to follow. Enter causal decision theory, which aims to give a satisfactory formal characterization of the correct, causal principle. What I take cases like The Murder Lesion and The Psychopath Button to show is that Lewisian CDT’s formal characterization of the informal principle isn’t satisfactory. The principle that Lewisian CDT actually endorses, *do what has the best expected outcome, holding fixed your current views about the causal structure of the world*, isn’t quite the right way of understanding the original principle, *do what’s most likely to bring about the best results*. 
My hope, then, is that there will be an alternative formal theory which provides a better understanding of the appealing principle. I regret that I do not have such a theory to offer.
