Dental Erosion Among Children in an Istanbul Public School

Esber Çaglar, DDS, PhD  Betul Kargul, DDS, PhD  Ilknur Tanboga, DDS, PhD  Adrian Lussi, DDS, PhD

ABSTRACT
The aim of this study was to evaluate the prevalence, clinical manifestations, and etiology of dental erosion among children. A total of 153 healthy, 11-year-old children were sampled from a downtown public school in Istanbul, Turkey comprised of middle-class children. Data were obtained via: (1) clinical examination; (2) questionnaire; and (3) standardized data records. A new dental erosion index for children designed by O'Sullivan (2000) was used. Twenty-eight percent (n=43) of the children exhibited dental erosion. Of children who consumed orange juice, 32% showed erosion, while 40% who consumed carbonated beverages showed erosion. Of children who consumed fruit yogurt, 36% showed erosion. Of children who swam professionally in swimming pools, 60% showed erosion. Multiple regression analysis revealed no relationship between dental erosion and related erosive sources (P>.05). (J Dent Child 2005;72:5-9)

KEYWORDS: DENTAL EROSION PREVALENCE, FRUIT YOGURT, ISTANBUL, ORANGE JUICE, SWIMMING

Dental hard tissue loss is caused by a number of factors, including dental caries, trauma, and, increasingly, tooth wear—which can occur by abrasion, attrition, and erosion. Dental erosion is defined as a loss of dental hard tissue caused by acid and, in contrast to caries, without bacterial involvement. Erosion may be caused by intrinsic as well as by extrinsic factors. The intrinsic factors for dental erosion include vomiting, regurgitation, gastroesophageal reflux, or rumination. The extrinsic factors for dental erosion in childhood are related to acids of dietary or medicinal origins and also to behavioral factors.

The consumption of soft drinks such as acidic fruit juices, artificially sweetened fruit drinks, and carbonated beverages are the risk factors most significantly related to this dental hard tissue defect. Lifestyle and behavior differences must also be considered important in the etiology of dental erosion. Epidemiological studies have shown that the prevalence of dental erosion in children varies widely between 2% and 57%.

As a candidate for the European Union, Turkey has undergone especially rapid development, with commensurate changes in lifestyle and diet. These changes are likely to cause substantial increases in the sale and consumption of acidic products, which could have an effect on children's oral health. This study's objective was to evaluate the prevalence, clinical manifestations, and etiology of extrinsic dental erosion in a sample of 11-year-old Istanbul schoolchildren.

METHODS
SAMPLE
The ethical clearance for this study was obtained from the Pediatric Dentistry Department Review Board of Marmara University Dental School, Istanbul, Turkey. The school was selected because of its established caries-preventive history and because it was representative of middle-class Istanbul children. The district's drinking water fluoride level was stated as <0.05 mg/l.

A total of 153 healthy 11-year-old schoolchildren (75 boys and 78 girls) were randomly sampled. Written informed consent was obtained from the parents. Children were asked to brush their teeth prior to examination for better oral monitoring. Oral examinations were carried out by 1 examiner in well-lit classrooms using a mirror and probe. Following the clinical examination, children completed an extensive questionnaire with the examiner and their parents (Table 1).

CLASSIFICATION
The dental literature provides useful clinical indices for the epidemiological recording of dental erosion. These indices seemed inadequate for the present study.

Dr. Çaglar is a dentist, Drs. Kargul and Tanboga are professors, Department of Pediatric Dentistry, School of Dentistry, Marmara University, Istanbul, Turkey; Dr. Lussi is professor, Department of Operative, Preventive, and Pediatric Dentistry, School of Dental Medicine, University of Berne, Berne, Switzerland.

A new, reproducible index for the measurement of erosion in children designed by O’Sullivan was used. This index scores:

1. Tooth surfaces affected (codes A to F):
   a. code A = labial or buccal only;
   b. code B = lingual or palatal only;
   c. code C = occlusal or incisal only;
   d. code D = labial and incisal/occlusal;
   e. code E = lingual and incisal/occlusal;
   f. code F = multisurface.

2. Dental erosion severity (codes 0 to 9):
   a. code 0 = normal enamel;
   b. code 1 = matte appearance of the enamel surface with no loss of contour;
   c. code 2 = loss of enamel only (loss of surface contour);
   d. code 3 = loss of enamel with exposure of dentine (dentinoenamel junction visible);
   e. code 4 = loss of enamel and dentine beyond dentinoenamel junction;
   f. code 5 = loss of enamel and dentine with exposure of the pulp;
   g. code 9 = unable to assess (e.g., tooth crowned or large restoration).

3. Surface area affected by erosion:
   a. code + = less than half of surface affected;
   b. code - = more than half of surface affected.

For the purpose of differential diagnosis, all detectable disorders of the dental hard tissue were recorded. These included:

1. Developmental defects of enamel
2. Dental fluorosis community index $F_{ci}$ (the fluorosis index described by Dean using natural light; the teeth were examined moist); and
3. Posteruptive disturbances of dental hard tissue, such as coronal damage from injury, or facets on incisal and occlusal surfaces of teeth resulting from attrition.

**QUESTIONNAIRE**

A questionnaire was prepared to elicit the following types of information:

1. Personal demographic details;
2. Dental and medical history;
3. Brushing frequency;
4. Habits of consuming beverages, fruits, ice cream, and fruit-flavored yogurt;
5. Time and type of consumption;

**DATA ANALYSIS**

All data were entered onto a computer using SPSS 10.0 for Windows statistical program. The association between dental erosion and factors was determined using a chi-square test. Besides the univariate analysis, multivariate regression analysis was performed. Statistical significance was established at the 5% level.

**RESULTS**

There was no significant difference between girls (32%) and boys (24%) regarding the prevalence of dental erosion ($P > 0.05$; Table 2). Eighty-five permanent teeth were scored as (A2-), (B1-), (C2+), (F2-), (F3+). The highest frequent code was (C2+), and the most severe erosion coded was (F3+; Table 3).

Eighty-six children consumed a mean of 1.76 ± 1.47 cups of acidic beverages per day; 38 consumed 1 cup of fresh orange juice daily, and 13 of these children showed erosion ($P = 0.09$); 12 consumed 2 cups of fresh orange juice daily, 3 of whom showed erosion ($P = 0.5$); and 36 consumed other acidulated beverages (carbonated beverages) per day.

Of the latter 36 children; 15 consumed 1 cup of carbonated beverages — 9 of whom showed erosion; and 17 consumed 2 cups of carbonated beverages, 4 of whom showed erosion ($P = 0.5$).
EROSION INDEX DESIGNED BY O’SULLIVAN WAS DESIGNED TO BE MORE APPROPRIATE FOR USE IN CHILDREN WHERE PATTERN AND PROGRESSION OF TOOTH TISSUE LOSS MAY BE DIFFERENT FROM ADULTS. TURMORE APPROPRIATE FOR USE IN CHILDREN WHERE PATTERN AND PROGRESSION OF TOOTH TISSUE LOSS MAY BE DIFFERENT FROM ADULTS.

DISCUSSION
A WIDE-RANGING PREVALENCE OF DENTAL EROSION HAS BEEN REPORTED IN BOTH PRIMARY AND PERMANENT DENTITIONS. THIS MAY BE DUE TO THE RELATIVELY SMALL NUMBER OF SUBJECTS IN THE MAJORITY OF STUDIES AND THE USE OF DIFFERENT CRITERIA FOR DIAGNOSIS. THE EROSION INDEX DESIGNED BY O’SULLIVAN WAS DESIGNED TO BE MORE APPROPRIATE FOR USE IN CHILDREN WHERE PATTERN AND PROGRESSION OF TOOTH TISSUE LOSS MAY BE DIFFERENT FROM ADULTS. TURKEY HAS A YOUNG POPULATION OF 20 MILLION CHILDREN AGED 0 TO 14 YEARS OLD. SALES MANAGEMENT TECHNIQUES AND ADVERTISEMENTS, THEREFORE, ARE MOSTLY ESTABLISHED REGARDING THE DIETARY HABITS OF CHILDREN.

CONSUMPTION OF ACIDIC FOODS AND BEVERAGES HAS BEEN SHOWN TO CONTRIBUTE TO DENTAL EROSION. IN THE PRESENT STUDY, 28% OF 11-YEAR-OLD CHILDREN SHOWED EROSION. A NATIONWIDE STUDY IN THE UNITED KINGDOM FOUND THAT DENTAL EROSION OCCURRED IN 25% OF 11-YEAR-OLD CHILDREN ON THE PALATAL AND VESTIBULAR SURFACES OF UPPER INCISORS. DENTAL EROSION HAS BEEN REPORTED AT AN INCIDENCE OF 17% IN A TOTAL OF 1,010 CUBAN CHILDREN. IN SAUDI ARABIA, 31% OF 2-TO-5-YEAR-OLD BOYS AND 26% OF 12-TO-14-YEAR-OLD BOYS SHOWED SIGNS OF DENTAL EROSION.

WHEN JUDGING EROSION FREQUENCY, ONE HAS TO DISTINGUISH BETWEEN EROSION EFFECTS AND OTHER TYPES OF DAMAGE TO DENTAL HARD TISSUE, ATRITION, INCISAL AND CORONAL FRACTURES, AND TOOTHBRUSH ABRASION. IN THE PRESENT STUDY, 3 CASES OF INCISAL FRACTURES OF ENAMEL AND DENTIN WERE RECORDED WHILE HYPOPLASIAS WERE NOT OBSERVED.

ACCORDING TO THE DATA COLLECTED FROM THE CHILDREN, 4 SOURCES EMERGED IN RELATION TO DENTAL EROSION: (1) FRESH ORANGE JUICE CONSUMPTION; (2) CARBONATED BEVERAGE CONSUMPTION; (3) FRUIT YOGURT CONSUMPTION; AND (4) SWIMMING. CONSUMPTION OF OTHER FRUIT JUVES, FRUITS, AND ICE CREAM WAS RATHER NEGIGEABLE. IT HAS BEEN REPORTED THAT ORANGE JUICE AND CARBONATED BEVERAGES WERE IMPORTANT ETIOLOGICAL FACTORS OF DENTAL EROSION. IT IS CLEAR THAT ORANGE JUICE HAS OBVIOUS HEALTH AND NUTRITIONAL BENEFITS FOR GROWING CHILDREN. THE DELETERIOUS EFFECTS OF ORANGE JUICE ON THE POPULATION’S ORAL HEALTH WILL ONLY BE OVERCOME WHEN DENTISTS AND THE POPULATION ARE THOROUGHLY ACQUAINTED WITH AND INFORMED ABOUT THE RISKS INVOLVED.

IN THE PRESENT STUDY, 32% OF CHILDREN WHO CONSUMED ORANGE JUICE SHOWED EROSION WHILE 40% OF CHILDREN WHO CONSUMED CARBONATED BEVERAGES SHOWED EROSION. LINNETT AND SEOI FOUND THAT ORANGE JUICE CAUSED LESS EROSION THAN CARBONATED COKE BEVERAGES. MATHEW ETC HAD SIMILAR FINDINGS REGARDING EROSION EFFECTS OF FRUIT JUVES AND CARBONATED DRINKS.

IN THE PRESENT STUDY, NO RELATIONSHIP BETWEEN THE CONSUMPTION OF ORANGE JUICE, CARBONATED BEVERAGES AND DENTAL EROSION WAS FOUND. IT SHOULD BE NOTED, HOWEVER, THAT MOUTH RINISING SHOULD BE RECOMMENDED AFTER CONSUMING ANY ACIDIC DRINK. OF THE CHILDREN WHO CONSUMED FRUIT YOGURT, 36% SHOWED DENTAL EROSION. IT HAS BEEN SHOWN, HOWEVER, THAT MILK PRODUCTS DO NOT CAUSE DEMINERALIZATION BECAUSE OF THEIR HIGH CALCIUM AND PHOSPHATE CONTENT, ALTHOUGH THIS IS ALSO DEPENDENT ON THE PRODUCT’S pH VALUE. IN THE PRESENT STUDY, UNIVARIATE AND MULTIVARIATE REGRESSION ANALYSIS SHOWED THAT CONSUMING FRUIT YOGURT WAS NOT ASSOCIATED WITH THE OCCURRENCE OF EROSION.

IMPROPER MONITORING OF pH IN GAS CHLORINATED SWIMMING POOLS HAS BEEN REPORTED TO BE THE CAUSE OF DENTAL EROSION IN COMPETITIVE SWIMMERS. CENTERWALL ET AL. SHOWED THAT, DESPITE DAILY pH MEASUREMENTS, THE POOL WATER’S pH HAD, AT TIMES, BEEN ALLOWED TO DROP TO AS LOW AS 2.7. MILOSEVIC ET AL. FOUND THE PREVALENCE OF DENTAL EROSION TO BE 36% IN SWIMMERS. IN THE PRESENT STUDY, 60% OF CHILDREN WHO SWAM PROFESSIONALLY IN CHLORINATED SWIMMING POOLS, BOTH IN SUMMER SCHOOL AND ALL THROUGHOUT THE YEAR, SHOWED DENTAL EROSION.

Twenty-two children consumed a mean of 2.68±0.27 cups of fruit yogurt per week, 8 of whom showed erosion (P=.2). Prevalence of dental erosion in relation to consumption of fruits and ice cream was stated as negligible (P>.05). Four of the 9 children who used straws showed erosion.

Twenty-five children swam professionally in the summer in chlorinated swimming pools, and 15 of them showed erosion (P=.3). Five of these children swam year round in chlorinated swimming pools, 3 of whom showed erosion.
This section will address biological and behavioral factors that must also be considered important in the etiology of dental erosion. It makes sense that a diet composed of foods or beverages with a low pH value would have erosive effects on human teeth. pH alone, however, is not a good indicator of any substance's erosive potential. Buffering capacity, fluoride, calcium, and phosphate content play a biological role in the process of erosion. Unusual drinking, eating, and swallowing habits, which increase the direct contact time of acidic foods and beverages with the teeth, are considered to be behavioral factors that increase the risk of dental erosion. Time of consumption (such as bedtime) has also been implicated. Direct contact time of erosive sources might be limited by use of a straw. In the present study, however, 44% of children who used straws showed erosion. Several case reports indicating that unusual methods of drinking fruit juice with a straw caused marked erosion of the anterior teeth. It is important to learn more about the etiology of erosion lesions before they can be accurately diagnosed, confidently treated, and, more importantly, prevented. Early diagnosis of the process and adequate preventive measures are, therefore, important. Personal interviews may give better information about dietary habits. Preventive advice to children, teenagers, parents, and health care providers should include a warning about the dangers of erosive sources to the teeth.

CONCLUSIONS

In the present study—using erosion as the dependent variable and carbonated beverages, fruits, fruit juices, ice cream, fruit yogurts, and swimming as independent factors—analysis revealed no statistically significant association between dental erosion and related erosive sources.
