Abstract: *A new record of brook lamprey is reported from the Adriatic slope of central Italy (river Potenza near Pioraco village, Marche region). Ammocoetes were compared with materials of the two brook lamprey species which occur in Italy. The Pioraco population appears to be more related to the padano-venetian one than to the other from the tuscan-latium district. The definitive identification will be given after the examination of transformed or adult specimens from the new locality. The zoogeographic implications of the record are discussed.*
